UC8251

All-in-one driver IC w/ Timing Controller for

White/Black/Red Dot-Matrix Micro-Cup ESL

INTRODUCTION

The UC8251 is an all-in-one driver with timing controller for ESL. Its output is of 1-bit white/black and 1-bit red resolution per pixel. The timing controller provides control signals for source driver and gate driver.

The DC-DC controller allows it to generate the source output voltage VSH/VSL (±2.4V~±15.0V) and VDHR (2.4V~15.0V). The chip also includes an output buffer for the supply of the COM electrode (AC-VCOM or DC-VCOM). The system is configurable through a 3-wire/4-wire (SPI) serial interface.

MAIN APPLICATIONS

Note: (1) All other register addresses are invalid or reserved by UltraChip, and should NOT be used.

(2) Any bits shown here as 0 must be written with a 0. All unused bits should also be set to zero. Device malfunction may occur if this is not done.

(3) Commands are processed on the 'stop' condition of the interface.

(4) Registers marked 'W/R' can be read, but the contents are written when the SPI command completes – so the contents can be read and altered. The user can subsequently write the register to restore the contents following an SPI read.

Source: First active source = X (If HRES[7:0]>160, X=0; otherwise, X=8)
Last active source = HRES[7:0] - 1 + X (If HRES[7:0]>160, X=0; otherwise, X=8)

Example: For 128 (source) x 272 (gate), assuming HST[7:3]=0, VST[8:0]=0

Gate: First active gate = G0,
Last active gate = G271 (VRES[8:0] = 272; 272 - 1= 271)

Source: First active source = S8, (HRES[7:0][160 therefore X=8)

HOST INTERFACES

UC8251 provides 3-wire/4-wire serial interface for command and display data transferred from the MCU. The serial interface supports 8-bit mode. Data can be input/output by clocks while the chip is active (CSB =LOW). While input, data are written in order from MSB at the clock rising edge. When too many parameters are input, the chip accepts only defined parameters, and ignores undefined ones.

BS	Interface	CSB	DC	SCL	SDA
High	3-wire SPI	Available	Fix to GND	Available	Available
Low	4-wire SPI	Available	Available	Available	Available

3 wire SPI format

Data / Command is recognized with the first bit transferred. Data are transferred in the unit of 9 bits. To prevent malfunction due to noise, it is recommended to set the CSB signal to HIGH every 9 bits. (The serial counter is reset at the rising edge of the CSB signal.)

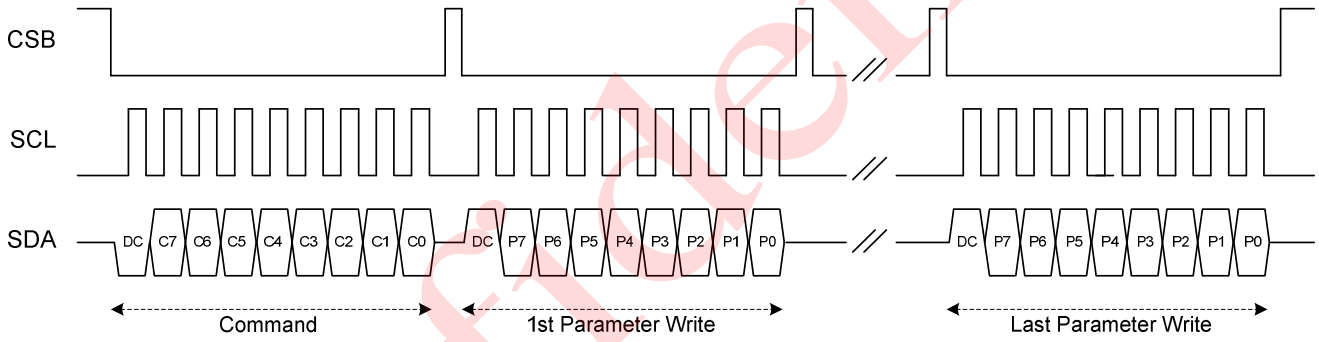

Figure: 3-wire SPI write operation

The MSB bit of data will be output at SDA pin after the 1st SCL falling edge, if the 1st input data at SDA is high. Only in the case of OTP data read, the 1st packet of output data are dummy data.

4 wire SPI format

Data / Command is recognized with DC pin. Data are transferred in the unit of 8 bits. To prevent malfunction due to noise, it is recommended to set the CSB signal to HIGH every 8 bits. (The serial counter is reset at the rising edge of the CSB signal.)

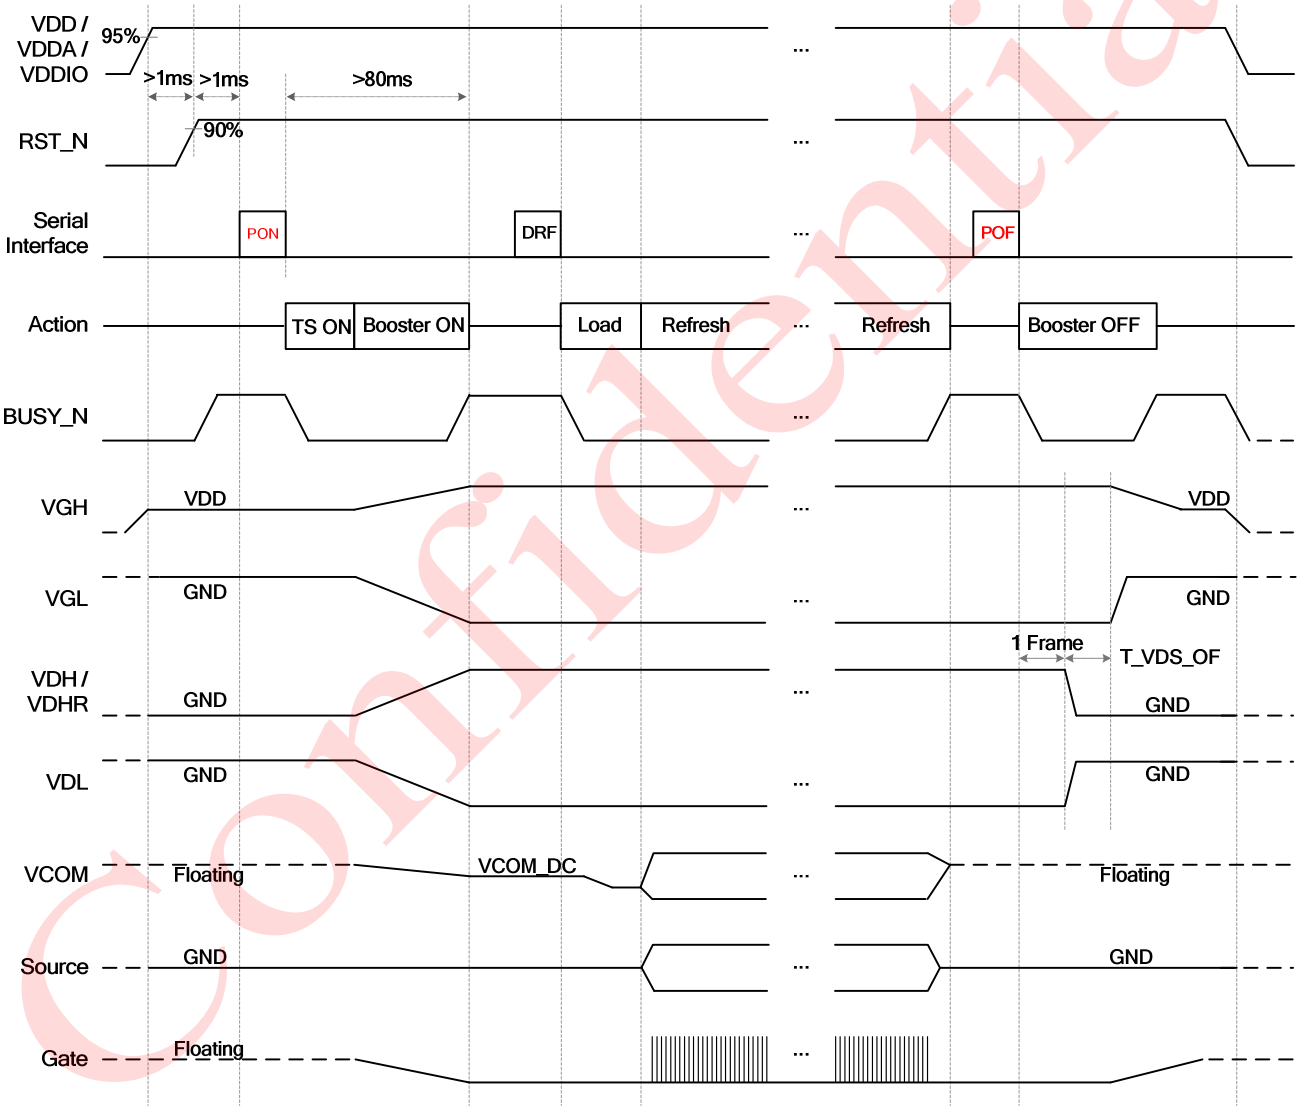
POWER MANAGEMENT

Power ON/OFF Sequence

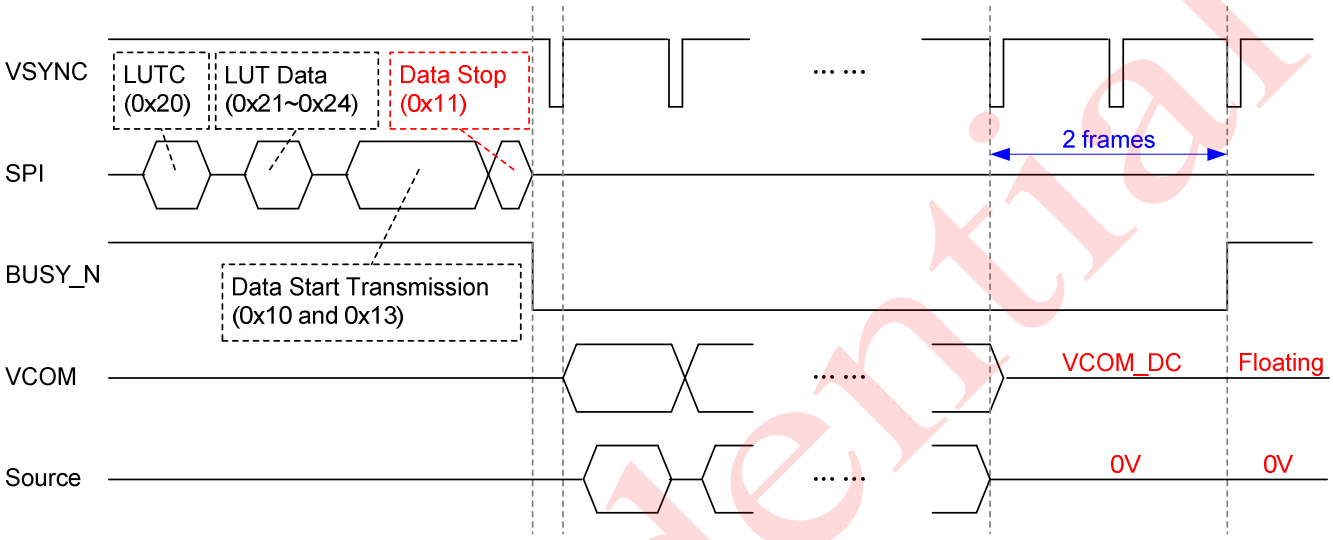
1. Temperature sensor will be activated automatically for one-time sensing before enabling booster.
2. After refreshing display, VCOM will be set to floating automatically.
3. In OTP mode (REG=0), the LUT in OTP will be copied to register automatically after the DSP/DRF command.
4. After RST_N rising, the waiting time for internal initial processing, greater than 1mS, is necessary. Any commands transmitted to chip during this time will be ignored.



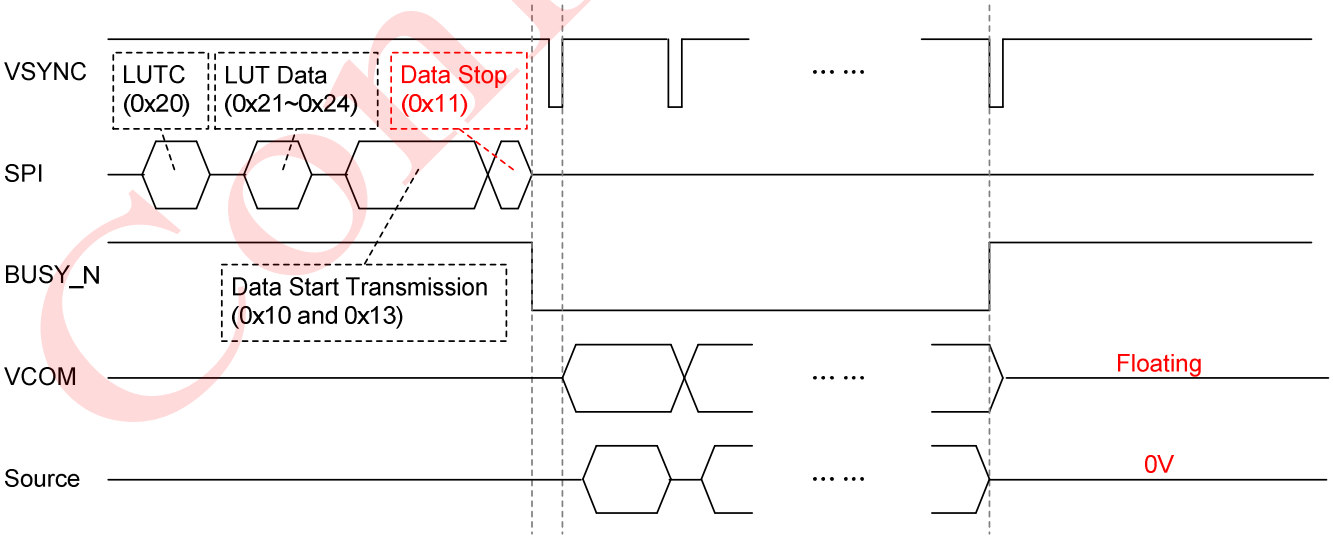
Data Transmission Waveform

Example 1: After 3 cases, the driver will send 2 frame VCOM and data to 0 V.

1. All 7 LUT groups (KW mode) or 10 LUT groups (KWR mode) complete.
2. Meet the group whose Times to Repeat =0
3. Meet the group whose all Number of Frames =0



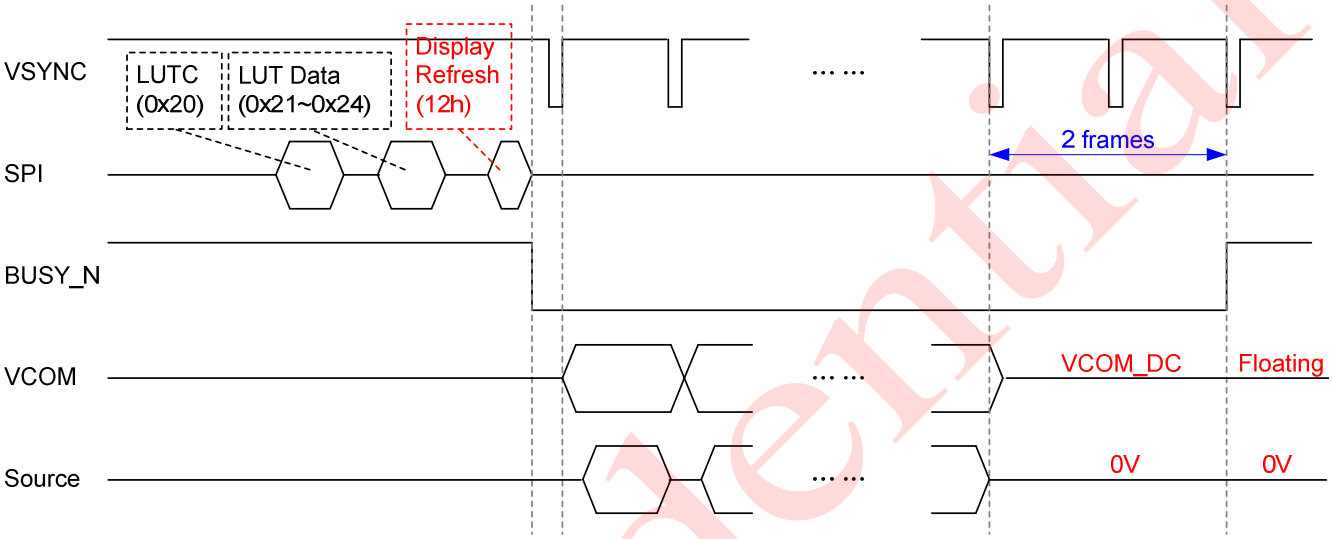
Example2: While level selection in LUT (LUTC only) is "1111_1111b", the driver will float VCOM.



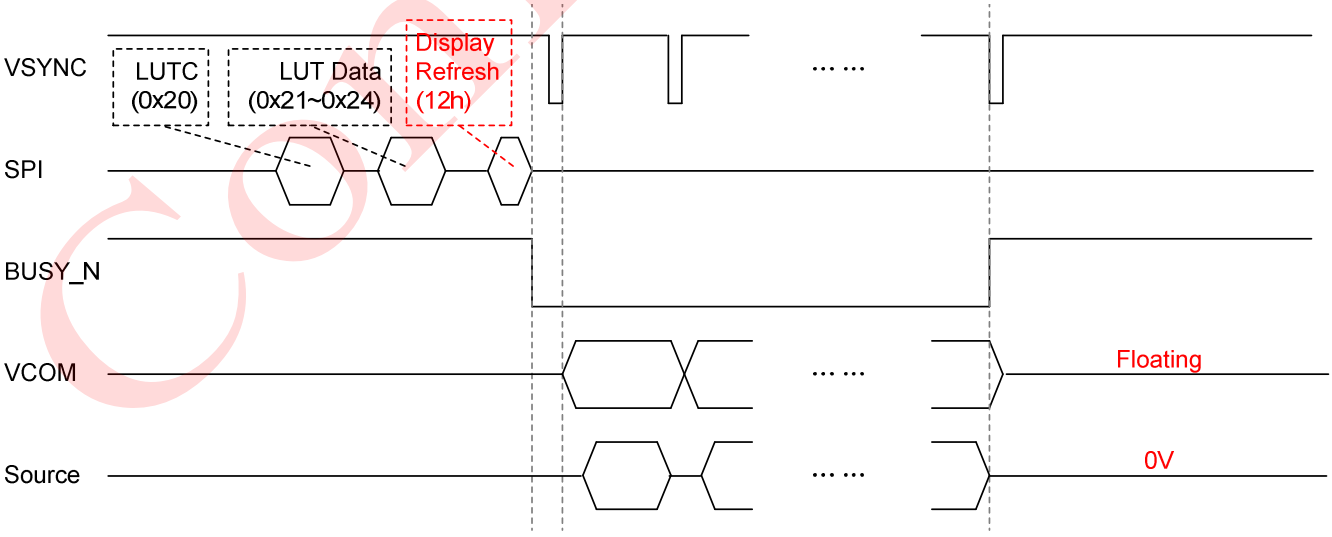
Display Refresh Waveform

Example 1: After three cases, the driver will send 2 frames VCOM and data to 0 V.

1. All 7 LUT groups (KW mode) or 10 LUT groups (KWR mode) complete.
2. Meet the group whose Times to Repeat = 0
3. Meet the group whose all Number of Frames = 0



Example2: While level selection in LUT (LUTC only) is “1111_1111b”, the driver will float VCOM.



BUSY_N Signal

Commands, except reading command, are restricted by refreshing display (DRF / DSP) as listed in the following table.

BUSY_N is used to represent the status of internal action. Commands activating internal operation or calculation will cause BUSY_N falling to LOW. After actions completed, BUSY_N will return to HIGH.

OTP ADDRESS MAPPING

The size of the internal One Time Programmable (OTP) memory is 8K bytes, and the address is from 0x0000 to 0x1FFF. The unprogrammed bit is logic 1. Only the bit at logic 1 can be programmed to logic 0, but the bit at logic 0 cannot be converted to logic 1.

There are 2 areas (0x0FA9~0x0FEF, 0x1FA9~0x1FEF) are reserved for user defined. Write all 0xFF of data to skip the 2 areas. The recommended voltage of VPP during programming is 8.25V. In the other condition except for programming, let VPP floating or be connected to GND. The maximum current of VPP during programming is 5mA.

There are 2 banks in the internal OTP, and each bank has 4K bytes storage memory. The formats of each bank are the same, and the selection of bank is controlled by Check Code (0x0000 and 0x1000). Bank1 has higher priority than Bank0. The 2 banks are used for two times programming.

COMMAND DEFAULT SETTING

This function can modify the default value of command registers by the OTP content between address 0x0001~0x0013 (or 0x1001~0x1013). The data of address 0x0001 (or 0x1001) is the enable key of the function. Changing default value function is used to reduce the initial code length executed by the microcontroller.

LUT FORMAT IN OTP

There are 12 TRs (temperature range) in a bank. Each TR has independant frame rate, voltage, XON settings and LUTs. The fomat of LUT is different in different mode. In KWR mode, there are only 4 LUTs including LUTC, LUTR, LUTW and LUTK in TRs. LUTC & LUTR have 10 states. However LUTW & LUTK has only 7 states. In KW mode, there are 5 LUTs including LUT, LUTWW, LUTKW, LUTWK and LUTKK in TRs. All LUTs have same number of state.

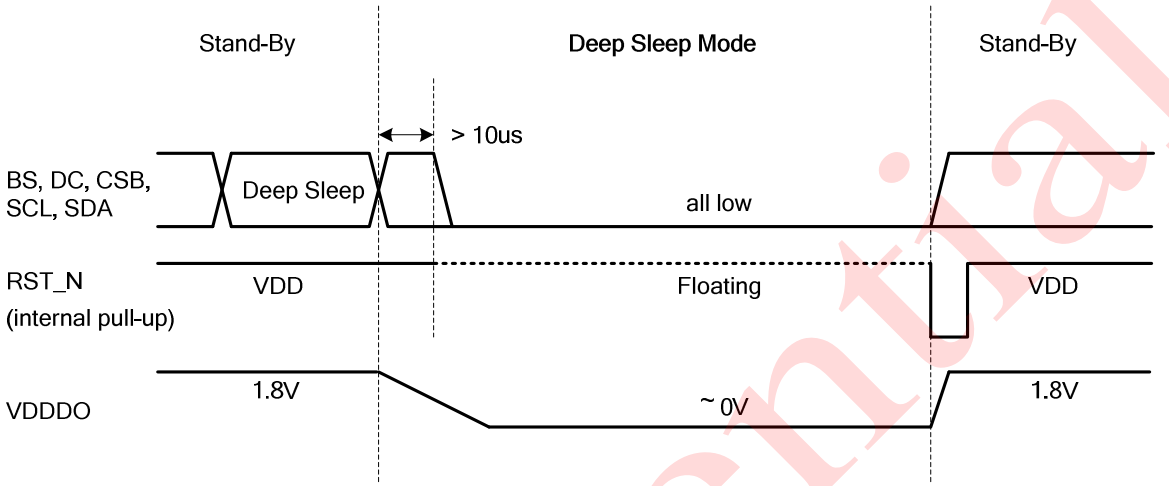
DEEP SLEEP MODE

After deep sleep command (R07H) is transmitted, UC8251 enter “Deep Sleep Mode”, and leaves by RST_N falling. In “Deep Sleep Mode”, the control signals are recommended tied to 0v to avoid IO leakage current. And the die must be keep away from light which causes photoelectric effect to make internal nodes unstable.



PANEL BREAK CHECK

The panel break check (PBC) function is accomplished by testing the connection of the ITO along panel edge. If the panel is broken, the loop ITO may be cut off. The connection check is judged by signal transmission from CHKGO to CHKGI.

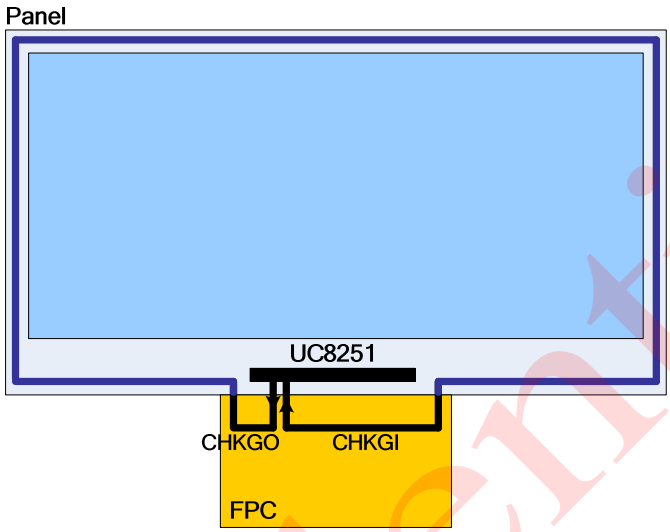


Figure: Panel break check layout example

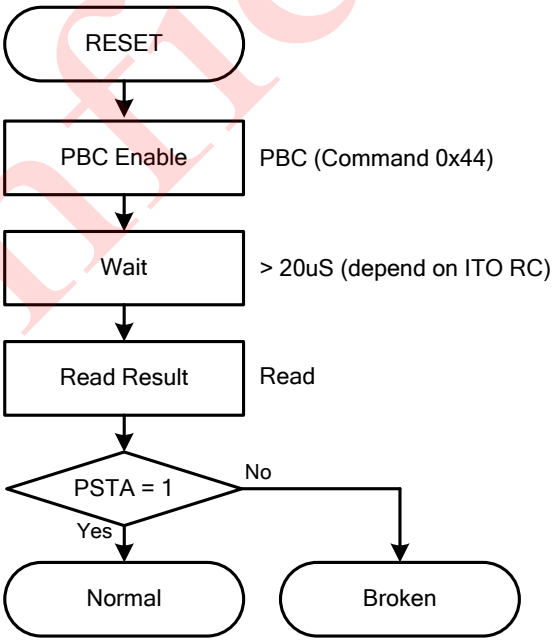

Figure: Panel Break Check (PBC) Sequence

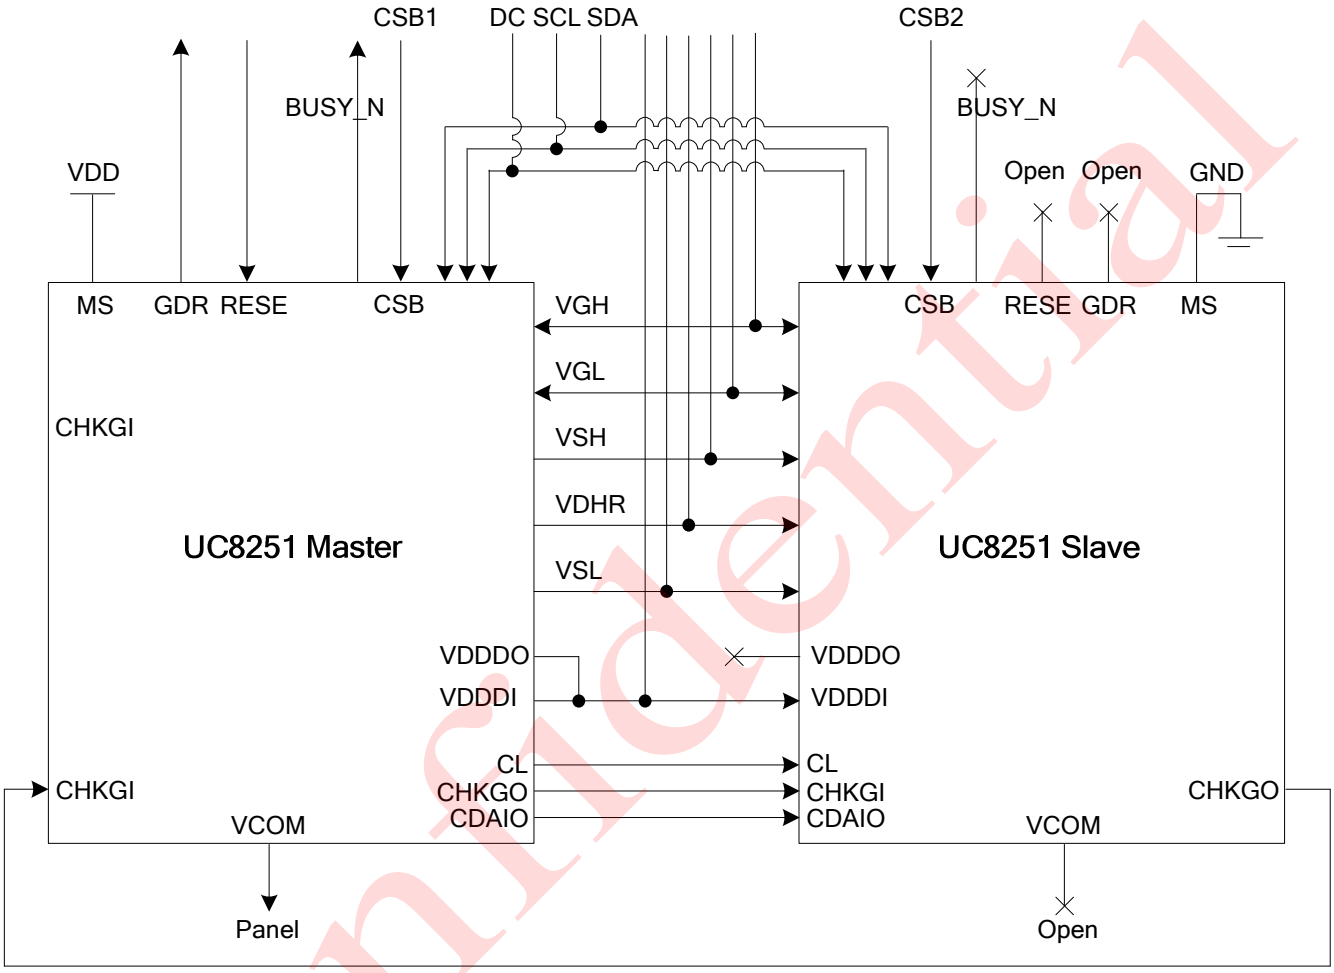
CASCADE APPLICATION CIRCUIT



All commands sent to **Master** must be also sent to **Slave** except for data writing (DTM1 and DTM2). The display data must be separated to two parts, one is for **Master** and another is for **Slave**. They are transmitted to **Master** and **Slave** individually by using CSB1 and CSB2.
